

Each bug got fixed.

Nobody noticed they kept coming back.

A bug gets logged, assigned, fixed and closed. A few weeks later something very similar shows up again — different ticket, different wording, sometimes found while testing a different flow.

After this, nobody opens the log again.

I built this for the PM, not the QA team.

QA and engineers already see every bug — they work with them every day. The person who misses the bigger picture is the one deciding what the team works on next.

If it was built for QA	Built for the PM
Shows bug statistics	Helps decide what to fix next
Sorts by how many, how old	Sorts by how much users are affected
You open it when you need it	It reaches you every cycle
Tells you what broke	Tells you where to spend time

Halfway in, I was asking the wrong questions.

I was asking testers to work out which component was at fault. That is how an engineer thinks about a bug. A tester only knows what they were doing and what went wrong — and a guess here would break everything built on top of it.

what I first asked testers

Component at fault

Defect type

Severity: blocker / major / minor / cosmetic

what I changed it to

What were you trying to do?

What happened instead?

Could you continue?

If two testers rate the same bug differently, both can still be right. “Could you continue?” only has one honest answer.

The technical details did not go away. They moved to the engineer, who actually knows the answer.

What the PM actually sees.

Not every bug. Not every number. Only the problems that keep coming back, sorted by how much they affect users.

recurrence	defect density	escape rate	verified fixed
44%	16%	—	71%
15 of 34 repeat	per case run	too few to rate	first cycle on

Pattern	Defects	Trend	Weight
Profile data missing after signup People finish signing up and their saved details aren't there.	7		42
Multi-step signup rejects valid entries Valid phone numbers refused with no message saying why.	5		30
Buttons unreachable on small screens On phones the main button sits below the fold.	6		18

You can see it repeating

Five bars, one for each cycle. This problem came back three cycles in a row.

Sorted by impact, not count

A signup problem with 5 bugs sits above a settings problem with 6.

It says when it cannot tell you

Escape rate shows a dash. Only 3 production bugs were logged, which is too few to work with.

What I decided not to build.

No bug tracker — teams already have one

No test writing, no CI setup

No suggestions on how to fix a bug

No AI-written sprint summaries

No importing old bug data

It would look much better in a demo. But old bug records do not have the details needed to group them properly. And if the first thing a PM sees turns out to be wrong, they probably will not trust it again.

One input, one output

If the PM reads it, agrees with it, and still changes nothing, then it has not really helped.

It would just be the same ignored data, shown a bit better.
